

Metal LB

This section is to get metallb setup and working for a bare metal setup.

Let create the namespace

```
kubectl create namespace metallb-system  
kubectl label namespace metallb-system pod-security.kubernetes.io/enforce=privileged
```

We will use helm for ease of upgrades and the initial install. First, we need to add the repo.

```
helm repo add metallb https://metallb.github.io/metallb
```

Now, install metallb with helm.

```
helm install metallb metallb/metallb -n metallb-system
```

We need to choose a pool of IP addresses that metal lb can hand out for the type LoadBalancer. In my case, I really just want this for nginx ingress. We need to create the following yaml file to apply to the API.

```
apiVersion: metallb.io/v1beta1  
kind: IPAddressPool  
metadata:  
  name: main-pool  
  namespace: metallb-system  
spec:  
  addresses:  
    - 192.168.249.10-192.168.249.11  
---  
apiVersion: metallb.io/v1beta1  
kind: L2Advertisement  
metadata:  
  name: l2-lb  
  namespace: metallb-system
```

Lets verify everything is up and running.

```
kubectl get pods -n metallb-system
```
